## Modelling Blast Emissions for Open Pit Mining

Presentation to AWMA Ontario Section

### Air Quality and Environmental Acoustic Modelling Conference

October 22, 2013  
Toronto, Ontario, Canada

Alex Breido, Ph.D., P.Eng.

AMEC Environment & Infrastructure  
a Division of AMEC Americas Limited

### Overview of Presentation

- Shift in mentality: Why air emissions became so important for large scale mining projects
- Type of emission sources and why blasting in OP is so essential
- Contaminants generated by blasting
- Emissions estimate: the road to success with no clear direction
- Modelling Input:
  - ✓ Surface size and shape of an OP source
  - ✓ Base elevation
  - ✓ Effective depth and release height
  - ✓ Blasting time
  - ✓ Meteorological data
- Modelling Results
- Discussion

Mining Projects in Ontario 

The slide titled "Ring of Fire Exploration" features a central map of Ontario with a red ring highlighting the Ring of Fire area. Text on the slide includes: "Located within Ontario's Far North", "Remote, west edge of Lowlands, no power or access", "Approx. 35,000 claim units, covering an area of 6000 km<sup>2</sup>", "25 companies currently hold claims in the Ring of Fire belt", "Area of most intense exploration is 15-20 km long", and "Chromite and nickel the most significant development opportunities". A list of "SIGNIFICANT MINERAL DISCOVERIES IN THE RING OF FIRE AREA" includes Copper-zinc, Nickel-copper-platinum, Chromium-iron-vanadium, and Gold. The slide also includes the Ontario logo and "ONTARIO CANADA".

3

Shift in Mentality 

- Scale of Open Pit (OP) mining projects in Ontario:
  - ✓ Existing OP mines: 900 – 5,000 tpd of ore
  - ✓ Projects under approval: up to 60,000 tpd of ore
- EA and ECA phases of a mining project
- Surface rights based on air dispersion modelling
- Public concerns regarding air emissions generated by mining
- Challenges to model and to submit an ECA (Air) application for an OP mining project:
  - ✓ ADMGO – OP is mentioned only once in the ISCST3 description
  - ✓ Procedure for Preparing an ESDM Report – OP is not mentioned at all

## Type of Emission Sources

- Mine site sources versus Mill site sources
- Fugitive Emissions
  - ✓ Roads
  - ✓ Stock piles
  - ✓ Tailing ponds
- Open Pit
  - ✓ Constantly changing dimensions of this source (L x W x H)
  - ✓ Orientation Angle
  - ✓ OP Effective Area - a hidden player

5

## Contaminants Generated by Blasting

Blast in Open Pit ([www.miningaustralia.com.au](http://www.miningaustralia.com.au))

- Bulk Emulsion – Ammonium Nitrate with Fuel Oil (ANFO)
- Carbon Monoxide (CO) – the contaminant produced in biggest quantity
- NO<sub>x</sub> – Nitric Oxide (NO) and Nitrogen Dioxide (NO<sub>2</sub>)
- SO<sub>x</sub> – less emitted contaminant
- PM – TSP and PM<sub>10</sub>
- Traces of Hydrogen Sulphide, Hydrogen Cyanide and Ammonia

6

## Emissions Estimate

- Amount of explosives used (kg) = amount of ore/rock (tonne) x powder factor (kg/tonne)
- Emission factors: US EPA, AP-42 data for NO<sub>x</sub> and CO is about 40 years old:
  - ✓ NO<sub>x</sub> – 8 kg/tonne
  - ✓ CO – 34 kg/tonne
- Emission factors provided by explosives supplier:
  - ✓ NO<sub>x</sub> – 3 kg/tonne
  - ✓ CO – 16 kg/tonne
- The approximate ratio of CO:NO:SO<sub>2</sub>:NO<sub>2</sub> was determined to be 500:27.5:5.5:1 (ACARP data)

7

## Modelling Input

- The size and the shape of an OP:
  - ✓ Irregularly-shaped pit areas should be presented by an equal area of rectangular shape
  - ✓ An open pit could not be subdivided
  - ✓ The size, shape and depth of the pit are changing over the live time of the mine

8

### Modelling Input

- Base elevation – the elevation of the top of the pit
- Effective depth = OP volume (m<sup>3</sup>) / OP surface area (m<sup>2</sup>)
- Release height – can't exceed the effective depth
  - ✓ No clear recommendations how to set this parameter
  - ✓ Sensitivity modelling runs demonstrate that this modelling parameter is related to an OP shape, orientation angle and a wind rose
- Blasting time – one hour difference is the difference between “pass” and “fail”
  - ✓ Winter and “the rest of the year” – different blasting schedule
- Local meteorological file – is a crucial part of an OP modelling project

9

### Modelling Results and Conclusions

- NO<sub>x</sub> 1 hr average – is the most critical contaminant in OP modelling (Ontario case)
- MOE's AAQC lists NO<sub>2</sub> whereas O.Reg. 419 standards apply to NO<sub>x</sub> (note both are based on health effects of NO<sub>2</sub>)
- NO<sub>2</sub> criteria and NO<sub>x</sub> limits are same values
- EA assessment considers only NO<sub>2</sub>, however, it is prudent to also evaluate NO<sub>x</sub> to ensure site will be compliant with O.Reg. 419
- To determine NO<sub>2</sub> impact from blasting the AERMOD's non-default NO<sub>x</sub> to NO<sub>2</sub> OLM conversion method used, resulting for some modelling scenarios in a decreased 1-hour POI concentration by almost 90%
- Sensitivity modelling runs (NO<sub>x</sub> 1 hr average) – the only way how to come up with the worst case operational scenario

10

**Modelling Results and Conclusions (cont.)**

- Concurrent blasting operations in adjacent pits considerably increase the number of modelling scenarios and the importance of sensitivity analyses
- Modelling results will help to develop the operational/blasting procedures and the BMPP requirements
- The duration of the project can be affected by OP blasting modelling
- The “surface rights” of the project could be established based on OP dispersion modelling
- The modelling guidance documents need to be revised and updated to incorporate OP production operations/blasting
